

 Detailed database models are implemented with database management system (DBMS)

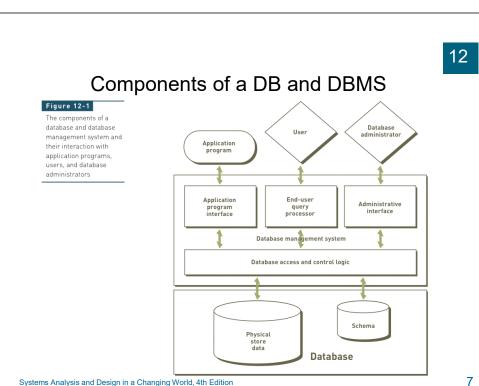

# Databases and Database Management Systems

 Databases (DB) – integrated collections of stored data that are centrally managed and controlled

- Entity or class attribute( eq. names, prices ).
- Relationships among the entities or classes (eq. which orders belong to which customers).
- Stores descriptive information about data, such as field names, restrictions on allowed data and access control to sensitive information.

# Databases and Database Management Systems (Cont.)

- The database (DB) consists of two related information store:
  - The physical data store: used by DBMS to store the raw bits and bytes of a database.
  - The schema: description of structure, content, and access controls of a physical data store or DB.
- Database management system (DBMS) system software that manages and controls access to database (eg. Microsoft access, Oracle, DM2)

Systems Analysis and Design in a Changing World, 4th Edition

12

6

# Important DBMS Capabilities

- Simultaneous access by multiple users and applications.
- Access to data without writing application programs (via a query language).
- Organizational data management with uniform access and content controls

12

5

### **Relational Databases**

- Relational database management system (RDBMS): organizes data into tables or relations
- Tables are two dimensional data structures
  - Tuples rows or records
  - Fields columns or attributes
- Tables have primary key field(s) that can be used to identify unique row of relational database table.
- Keys: A field that contains a value that is unique within each row of a RDBMS.

Systems Analysis and Design in a Changing World, 4th Edition

10

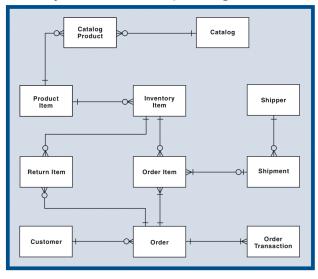

# **Designing Relational Databases**

- Create table for each entity type
- Choose or invent primary key for each table
- Add foreign keys to represent one-to-many relationships
- Create new tables to represent many-to-many relationships
- Define referential integrity constraints
- Evaluate schema quality and make necessary improvements
- Choose appropriate data types and value restrictions (if

### necessary) for each field

Systems Analysis and Design in a Changing World, 4th Edition

RMO Entity-Relationship Diagram (Figure 12-5)

# Represent One-to-Many Relationships by Adding Foreign Keys (in italics) (Figure 12-8)

Table	Attributes
Catalog	CatalogID, Season, Year, Description, EffectiveDate, EndDate
CatalogProduct	CatalogProductID, Price, SpecialPrice
Customer	AccountNo, Name, BillingAddress, ShippingAddress, DayTelephoneNumber, NightTelephoneNumber
InventoryItem	InventoryID, ProductID, Size, Color, Options, QuantityOnHand, AverageCost, ReorderQuantity
Order	OrderID, AccountNo, OrderDate, PriorityCode, ShippingAndHandling, Tax, GrandTotal, EmailAddress, ReplyMethod, PhoneClerk, CallStartTime, LengthOfCall, DateReceived, ProcessorClerk
Orderltem	OrderItemID, OrderID, InventoryID, TrackingNo, Quantity, Price, BackorderStatus
OrderTransaction	OrderTransactionID, Order/D, Date, TransactionType, Amount, PaymentMethod
ProductItem	ProductID, Vendor, Gender, Description
ReturnItem	ReturnItemID, OrderID, InventoryID, Quantity, Price, Reason, Condition, Disposal
Shipment	TrackingNo, ShipperID, DateSent, TimeSent, ShippingCost, DateArrived, TimeArrived
Shipper	ShipperID, Name, Address, ContactName, Telephone

# Entity Tables with Primary Keys (Figure 12-7)

Table	Attributes
Catalog	CatalogID, Season, Year, Description, EffectiveDate, EndDate
CatalogProduct	CatalogProductID, Price, SpecialPrice
Customer	AccountNo, Name, BillingAddress, ShippingAddress, DayTelephoneNumber, NightTelephoneNumber
Inventoryltem	InventoryID, Size, Color, Options, QuantityOnHand, AverageCost, ReorderQuantity
Order	OrderID, OrderDate, PriorityCode, ShippingAndHandling, Tax, GrandTotal, EmailAddress, ReplyMethod, PhoneClerk, CallStartTime, LengthOfCall, DateReceived, ProcessorClerk
Orderltem	OrderItemID, Quantity, Price, BackorderStatus
OrderTransaction	OrderTransactionID, Date, TransactionType, Amount, PaymentMethod
ProductItem	ProductID, Vendor, Gender, Description
ReturnItem	ReturnItemID, Quantity, Price, Reason, Condition, Disposal
Shipment	TrackingNo, DateSent, TimeSent, ShippingCost, DateArrived, TimeArrived
Shipper	ShipperID, Name, Address, ContactName, Telephone

Systems Analysis and Design in a Changing World, 4th Edition

12

# **Representing Relationships**

- Relational databases use foreign keys to represent relationships
- One-to-many relationship
  - Add primary key field of "one" entity type as foreign key in table that represents "many" entity type
- Many-to-many relationship
  - Use the primary key field(s) of both entity types
  - Use (or create) an associative entity table to represent relationship (Figure 12-9 in text book)

14

Figure 12-4	SNIP BETWEEN DATA IN I WO I ADIE	S

<ul> <li>When pri</li> </ul>	imary key value is changed	
	ensures no foreign key values in relate contain the same value	d

Relationship Retween Data in Two Tables

# **Enforcing Referential Integrity**

- Referential Integrity: describes a consistent state among foreign key and primary key(eg. An order must be from a customer).
- Every foreign key value also exists as a primary key value
- DBMS enforces referential integrity automatically after schema designer identifies primary and foreign keys

# **Evaluating Schema Quality**

High-quality data model has

Systems Analysis and Design in a Changing World, 4th Edition

- Uniqueness of table rows and primary keys
- Ease of implementing future data model changes (flexibility and maintainability)
- Lack of redundant data (database normalization)
- Database design is not objective or quantitatively measured; it is experience and judgment based

12

19

18

# **Database Normalization**

12

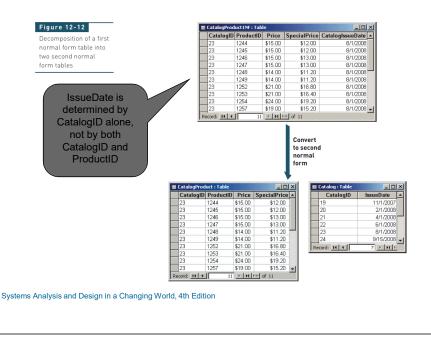

- Normalization: Ensures relational database schema quality by minimizing data redundancy.
- Normal forms minimize data redundancy
  - First normal form (1NF) no repeating fields or groups of fields.
  - Functional dependency one-to-one relationship between the values of two fields.
  - The relationship is formally stated as follows:

Field A is functionally depend on field B if for each value of B there is only one corresponding value of A

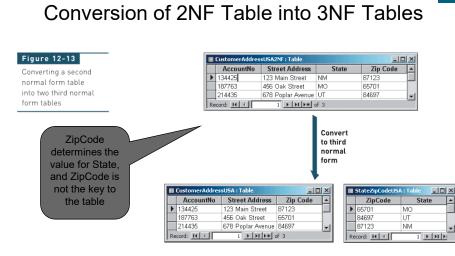

- 2NF in 1NF and if each non-key element is functionally dependent on entire primary key
- 3NF in 2NF and if no non-key element is functionally dependent on any other non-key element

21

# Decomposition of 1NF Table into 2NF Tables

12

# **Object-Oriented Databases**

- Direct extension of OO design and programming paradigm
- ODBMS stores data as objects or class instances and to interface with OO programming languages
- Direct support for method storage, inheritance, nested objects, object linking, and programmerdefined data types
- Object Definition Language (ODL)
  - Standard object database description language for describing structure and content of an object database

22

# Designing Object Databases

12

25

12

- Determine which classes require persistent storage
- Define persistent classes
- Represent relationships among persistent classes
- Choose appropriate data types and value restrictions (if necessary) for each field

Systems Applysis and	Decign in a	Changing World 4th Edition	
Systems Analysis and	Designina	Changing World, 4th Edition	L.,

# **Representing Relationships**

- Object identifiers
  - Used to identify objects uniquely
  - Physical storage address or reference
  - Relate objects of one class to another
- ODBMS uses attributes containing object identifiers to find objects that are related to other objects
- Keyword *relationship* can be used to declare relationships between classes

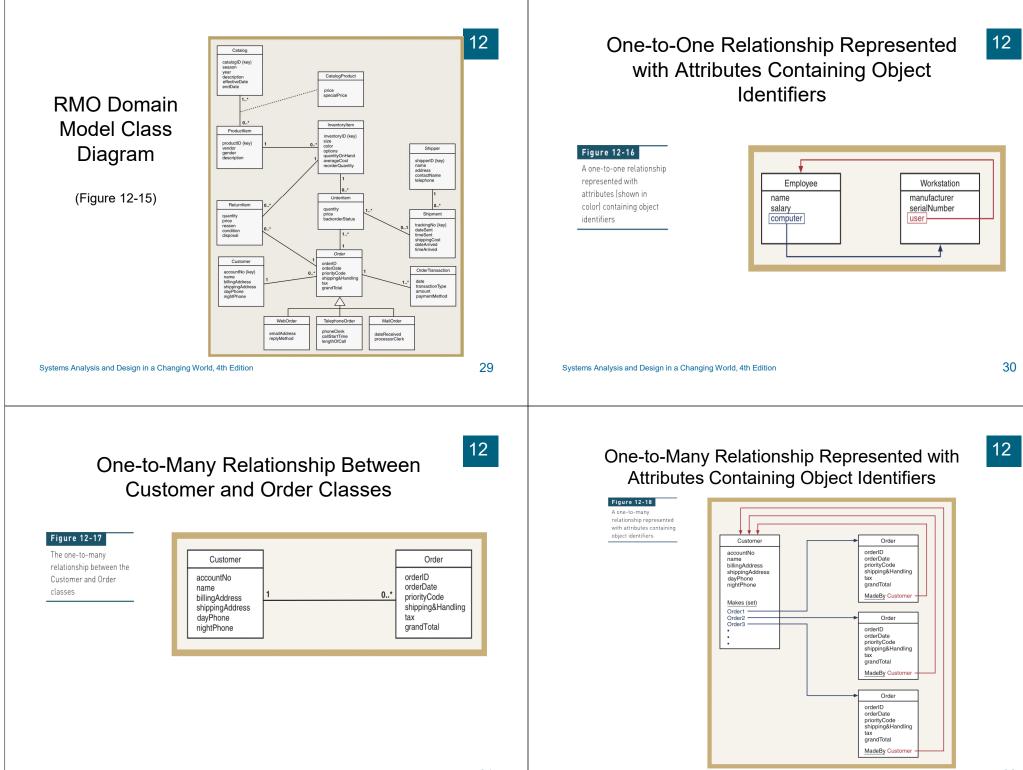

There are two types of classes for purpose of DM

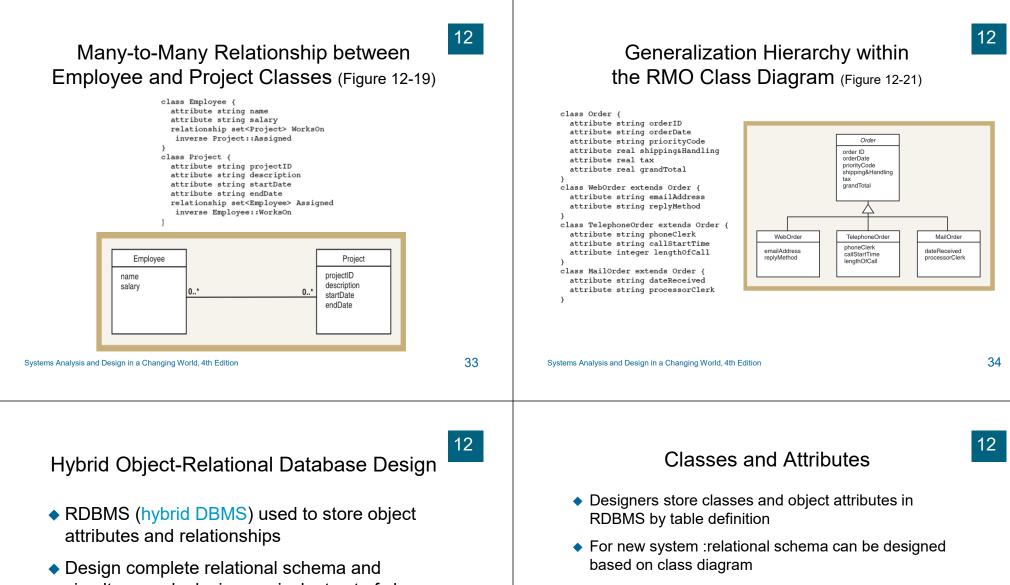

**Representing Classes** 

- Transient classes
  - Objects exist only during lifetime of program or process
  - Examples: view layer window, pop-up menu
- Persistent classes
  - Objects not destroyed when program or process ceases execution. State must be remembered.
  - Exist independently of program or process
  - Examples: problem domain( customer information, employee information).

- Representing Relationships (continued)
- Advantages include
  - ODBMS assumes responsibility for determining connection among objects
  - ODBMS assumes responsibility for maintaining referential integrity
- Type of relationships
  - 1:1, 1:M, M:M (one-to-one, one-to-many, many-tomany)
  - Association class used with M:M

26

- simultaneously design equivalent set of classes
- Mismatches between relational data and OO
  - Class methods cannot be directly stored or automatically executed
  - Relationships are restricted compared to ODBMS
  - ODBMS can represent wider range of data types

- Table is created for each class
- Fields of each table same as attributes of class
- Row holds attribute values of single object
- Key field is chosen for each table
- ♦ อย่าถืมทำ EER Mapping (Class → Table)
  - Step 8 (เถือก Option ใหน 8A-8C)

Systems Analysis and Design in a Changing World, 4th Edition

# Data Types

- Storage format and allowable content of program variable, object state variable, or database field or attribute
- Primitive data types directly implemented
  - Memory address (pointer), Boolean, integer, and so on
- Complex data types user-defined

Systems Analysis and Design in a Changing World, 4th Edition

Dates, times, audio streams, video images, URLs

# 12

43

41

12

Subset of Oracle RDBMS Data Types

### Figure 12-26

A subset of the data types available in the Oracle relational DBMS

Description
Fixed-length character array
Variable-length character array
Real number
Date and time with appropriate checks of validity
Variable-length character data up to 2 gigabytes
Binary large object (BLOB) with no assumption about format or content
Unique six-byte physical storage address

- Designer must choose appropriate data type for each field in relational database schema
- Choice for many fields is straightforward
  - Names and addresses use a set of fixed- or variable-length character arrays
  - Inventory quantities can use integers
  - Item prices can use real numbers
- Complex data types (DATE, LONG, LONGRAW)

Systems Analysis and	Design in a Chan	ging World, 4th	Edition
----------------------	------------------	-----------------	---------

12

42

# **Object DBMS Data Types**

- Use set of primitive and complex data types comparable to RDBMS data types
- Schema designer can create new data types and associated constraints
- Classes are complex user-defined data types that combine traditional concept of data with processes (methods) to manipulate data
- Flexibility to define new data types is one reason that OO tools are widely used

# **Distributed Databases**

- Rare for all organizational data to be stored in a single database in one location
- Different information systems in an organization are developed at different times
- Parts of an organization's data may be owned and managed by different units
- System performance is improved when data is near primary applications

#### Systems Analysis and Design in a Changing World, 4th Edition

Single Database Server Architecture (Cont.)

- Primary Advantages: Simplicity, because there are only one server to manage.
- Primary Disadvantages:
  - Server failure
  - Possible load of the server
  - No back up capabilities in the event of server failure.
- Poorly suited to applications that must be available on 24/7

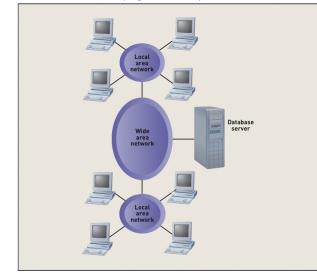

45

12

# Single Database Server Architecture

(Figure 12-27)

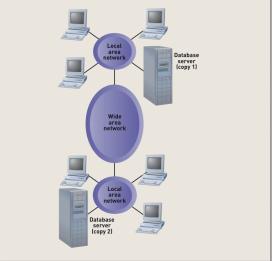

Systems Analysis and Design in a Changing World, 4th Edition

12

12

# Replicated Database Server Architecture

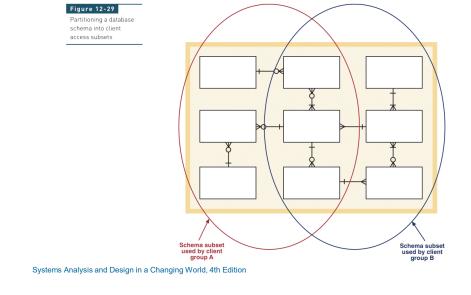

(Figure 12-28)

Systems Analysis and Design in a Changing World, 4th Edition

12

# Partitioning Database Schema into Client Access Subsets

Replicated Database Server Architecture

- Designers can eliminate delay in accessing distance database server.
- More fault tolerance.
- Load balancing.
- Primary Disadvantage:
  - Data inconsistency
- Database Synchronization: The process of ensuring consistency among two or more database copies.

## Summary

- Modern information systems store data in database and access and manage data using DBMS
- Relational DBMS is commonly used
- Object DBMS is increasing in popularity
- Key activity of systems design is developing relational or object database schema
- Relational database is collection of data stored in tables and is developed from entity-relationship diagram
- Object database stores data as collection of related objects and is developed from class diagram
- Objects can also be stored in RDBMS
  - RDBMS cannot store methods
  - RDBMS cannot directly represent inheritance
- Medium and larger information systems typically use multiple databases or database servers in various geographic locations

Systems Analysis and Design in a Changing World, 4th Edition
