**Abstract-** this paper discusses the several research methodologies that can be used in Computer Science (CS) and Information Systems (IS). The research methods vary according to the science domain and project field. However a little of research methodologies can be reasonable for CS and IS.

**Keywords-** Computer Science(CS), Information Systems (IS),Research Methodologies.

## 1. INTRODUCTION

Science is an organized or systematic body of knowledge [1]. Science embraces many different domains however those domains are related. As shown in fig1, Logic and mathematics sciences are the core of all sciences. From there and descending it emerge the natural sciences such as physic, chemistry and biology. In the next come the social sciences.

As [3] reported Computer Science (CS) should not be called as a science. Although CS is definitely a recent discipline, few will still argued that it is not provided with attributes to be qualified as a science. CS has its specificity and has its bases in logic and mathematics.

However CS is transversal to very different domains in science. To understand which research methodologies that can be used in CS and IS we have to understand the differences between CS and IS.

Computer science (CS) characterized as an empirical discipline, in which each new program can be seen as an experiment, the structure and behavior of which can be studied [4]. In particular, the field of CS is concerned with a number of different issues seen from a technological Perspective, e.g. theoretical aspects, such as numerical analysis, data Structures and algorithms; how to store and manipulate, the relationship between different pieces of software and techniques and tools for developing software .The field of Information Systems (IS) is concerned with the interaction between social and technological issues [5]. In other words, it is a field which focuses on the actual “link” between the human and social aspects (within an organization or other broader social setting), *and* the hardware, Software and data aspects of information technology (IT). In the next sections we will discuss the different methods of research methodology and its reasonability for the CS and IS domains.

## ***2. RESEARCH METHODS***

Before we start in discuss the different types of research methodologies we have to define the research. In an academic context, research is used to refer to the activity of a diligent and systematic inquiry or investigation in an area, with the objective of discovering or revising facts, theories, applications etc. The goal is to discover and disseminate new knowledge. There are several methods that can be used in CS and IS in next subsection we will show these methodologies.

### ***2.1 EXPERIMENTAL METHOD***

Experimental shows the experiments that will occur in order extract results from real world implementations. Experiments can test the veracity of theories. This method within CS is used in several different fields like artificial neural networks, automating theorem proving, natural languages, analyzing performances and behaviors, etc. It is important to restate that all the experiments and results should be reproducible. Concerning, for example, network environments with several connection resources and users, the experiments are an important methodology Also in CS fields and especially IS fields that take in consideration the Human-Computer Interaction. It is mandatory the usage of experimental approaches. If we use the experimental method in IS field we may need to use some methods or tools in conjunction with the experimental method. These methods or tools used to support and prove the legibility of the developed project. For example if a student wants to implement new

social network with new concepts or develop an existing social network, who he can measure the legibility of his implementation? The answer of this question consists of two parts according to the nature of the project. The technical issue is the first part of the project that can be tested by benchmarks like (availability, reliability, scalability, stability, , etc). The usability of the project is the second part of testing that needs a feedback from the users of the system; the results for the second part can be obtained by the statistical analysis of a questionnaire which is a tool the used in conjunction with the experimental method.

## **2.2 SIMULATION METHOD**

Simulation method used especially in CS because it offers the possibility to investigate systems or regimes that are outside of the experimental domain or the systems that is under invention or construction. Normally complex phenomena that cannot be implemented in laboratories evolution of the universe. Some domains that adopt computer simulation methodologies are sciences such as astronomy, physics or economics; other areas more specialized such as the study of non-linear systems, virtual reality or artificial life also exploit these methodologies. A lot of projects can use the simulation methods, like the study of a new developed network protocol. To test this protocol you have to build a huge network with a lot of expensive network tools, but this network can't be easily achieved. For this reason we can use the simulation method.

## **2.2 THEORETICAL METHOD**

The theoretical approaches to CS are based on the classical methodology since they are related to logic and mathematics. Some ideas are the existence of conceptual and formal models (data models and algorithms). Since theoretical CS inherits its bases from logic and mathematics, some of the main techniques when dealing with problems are *iteration, recursion and induction*. Theory is important to build methodologies, to develop logic and semantic models and to reason about the programs in order to prove their correctness. Theoretical CS is dedicated to the design and algorithm analysis in order to find solutions or better solutions (performance issues, for example). Encompassing all fields in CS, the theoretical methodologies also tries to define the limits of computation and the computational paradigm. In other words we can say that we can use the theoretical method to model a new system. However the theoretical method can help in finding new mathematical models or theories, but this method still needs other methods to prove the efficiency of the new models or theories. For example when a student

need to develop a new classifier in AI by using the mathematical representation and theoretical method, he need to prove the efficiency of this model by using one of the previous methods.

#### ***4. CONCLUSION***

In this paper we try to differentiate between the domains of science and CS and IS to understand the best methods that can be used in CS and IS. Each project in CS or IS have its free nature so the paper give examples of different kinds of projects in CS and IS and the prober research methodologies that can used in these projects.
